Simulink Matlab Three Phase Fault

Inputs and Outputs. The three fault breakers are connected in wye between terminals A, B, and C and the internal ground resistor. If the Three-Phase Fault block is set to external control mode, a Simulink input is added to the block to control the opening and closing of the three internal breakers.

2 Answers. If selected, adds a fourth input port to the Three-Phase Fault block for an external control of the switching times of the fault breakers. The switching times are defined by a Simulink signal (0 or 1) connected to the fourth input port of the block. So the answer is any regular Simulink block, the signal has to be either 0 or 1.

This is more of a question about the Three-Phase fault block rather than about Simulink Real-Time. The parameter does not appear in the set of tun-able parameters for the target object because the block designer decided that the parameter should not be tun-able (and hence did not check the box for 'Tunable' in the mask parameter).

The fault that we are creating is single line to ground fault double line to ground fault and three lines to ground fault[1]. In this model we are using three phase source of 11kv, 50 Hz is connected to the series RLC load with an impedance of load in ohms, and it is connected through transmission lines.

This auto-generated seed value is set when you add a Voltage Source block from the block library to the model. When you make a new copy of the Voltage Source block from an existing one in a model, a new seed value is generated. The block sets the value using the MATLAB random number generator command shown above.
